Test Setup:	<p>For Radiated Below 1GHz</p> 												
	<p>Above 1GHz</p> 												
Test Mode:	Receive Mode												
Test Procedure:	<p><b>Below 1GHz test procedure:</b></p> <ol style="list-style-type: none"><li>1. On the test site as test setup graph above, the EUT shall be placed at the 1.5m support on the turntable and in the position closest to normal use as declared by the provider.</li><li>2. The test antenna shall be oriented initially for vertical polarization and shall be chosen to correspond to the frequency of the transmitter. The output of the test antenna</li></ol>												

- shall be connected to the measuring receiver.
3. The transmitter shall be switched on, if possible, without modulation under test.
  4. The test antenna shall be raised and lowered from 1m to 4m until a maximum signal level is detected by the measuring receiver. Then the turntable should be rotated through 360° in the horizontal plane, until the maximum signal level is detected by the measuring receiver.
  5. Repeat step 4 for test frequency with the test antenna polarized horizontally.
  6. Remove the transmitter and replace it with a substitution antenna (the antenna should be half-wavelength for each frequency involved).
  7. The center of the substitution antenna should be approximately at the same location as the center of the transmitter. At the lower frequencies, where the substitution antenna is very long, this will be impossible to achieve when the antenna is polarized vertically. In such case the lower end of the antenna should be 0.4 m above the ground.
  8. Feed the substitution antenna at the transmitter end with a signal generator connected to the antenna by means of a Non-radiating cable. With the antennas at both ends vertically polarized, and with the signal generator tuned to a particular test frequency, raise and lower the test antenna to obtain a maximum reading at the spectrum analyzer. Adjust the level of the signal generator output until the previously recorded maximum reading for this set of conditions is obtained. This should be done carefully repeating the adjustment of the test antenna and generator output.
  9. Repeat step 7 with both antennas horizontally polarized for each test frequency.
  10. Calculate power in dBm into a reference ideal half-wave dipole antenna by reducing the readings obtained in steps 7 and 8 by the power loss in the cable between the generator and the antenna, and further corrected for the gain of the substitution antenna used relative to an ideal half-wave dipole antenna by the following formula:  
$$\text{ERP(dBm)} = \text{Pg(dBm)} - \text{cable loss (dB)} + \text{antenna gain (dBd)}$$
where: Pg is the generator output power into the substitution antenna.

**Above 1GHz test procedure:**

	Different between above is the test site, change from Semi-Anechoic Chamber to fully Anechoic Chamber, and the test antenna do not need to raise from 1 to 4m, just test in 1.5m height.
Test Instrument:	Refer to Item 3.3
Test Result:	PASS

**Table D.2: Radar Detection Threshold Levels**

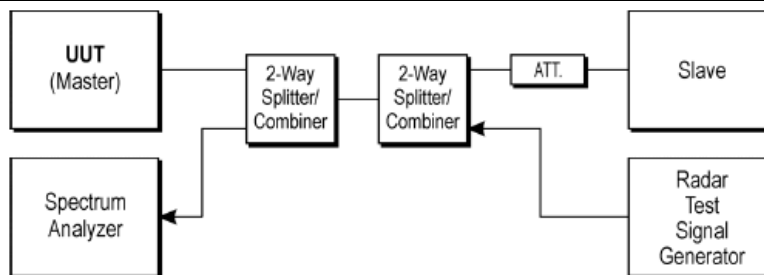

e.i.r.p. Spectral Density (dBm/MHz)	Value (see note 1 and note 2)
10	-62 dBm
NOTE 1: This is the level at the input of the receiver of an RLAN device with a maximum e.i.r.p. density of 10 dBm/MHz and assuming a 0 dBi receive antenna. For devices employing different e.i.r.p. spectral density and/or a different receive antenna gain G (dBi) the Radar Detection Threshold Level at the receiver input follows the following relationship: DFS Detection Threshold (dBm) = -62 + 10 - e.i.r.p. Spectral Density (dBm/MHz) + G (dBi); however the Radar Detection Threshold Level shall not be less than -64 dBm assuming a 0 dBi receive antenna gain.	
NOTE 2: Slave devices with a maximum e.i.r.p. of less than 23 dBm do not have to implement radar detection unless these devices are used in fixed outdoor point to point or fixed outdoor point to multipoint applications (see clause 4.2.6.1.3).	

The minimum required detection probability associated with a given radar test signal is defined in table D.5.

**Table D.5: Detection probability**

Parameter	Detection Probability ( $P_d$ )	
	Channels whose nominal bandwidth falls partly or completely within the 5 600 MHz to 5 650 MHz band	Other channels
CAC, Off-Channel CAC	99,99 %	60 %
In-Service Monitoring	60 %	60 %
NOTE: $P_d$ gives the probability of detection per simulated radar burst and represents a minimum level of detection performance under defined conditions. Therefore $P_d$ does not represent the overall detection probability for any particular radar under real life conditions.		

**Test Setup:**

**Figure 4: Set-up A**

**Test Procedure:**

1. Test performed with tested device in normal conditions. The UUT was tested as a master device.
2. The test "Set-up A" was used. Radar test signals are injected into the UUT. This set-up also contained an RLAN device operating in slave mode which is associated with the UUT. The insertion loss of the splitter/combiner has been taken into account.

**Test Instrument:**

Refer to Item 3.3

**Test Result:**

### 5.6.3.2. Test Data

**Note:** While the UUT was transmitting a test transmission sequence in accordance with clause 5.3.1.2 on the selected channel at a certain time T0, a single burst test signal was generated on selected channel using the reference DFS test signal defined in table D.3 and at a level of up to 10 dB above the level defined in clause 5.4.8.2.1.1. T1 denotes the end of the radar burst. The transmissions of the UUT following the end of the burst (T1) on the selected channel were observed for a period greater than to the Channel Move Time defined in table D.1. The aggregate duration (Channel Closing Transmission Time) of all transmissions from the UUT on selected channel during the Channel Move Time was compared to the limit defined in table D.1. T2 denotes the instant when the UUT has ceased all transmissions on the selected channel. Following instant T2, the selected channel was observed for a period equal to the Non-Occupancy Period (T3-T2) to verify that the UUT does not resume any transmissions on this channel.
